

A better way to care for patients with delirium in hospital

Delirium is an acute disturbance of consciousness, attention and cognition that tends to fluctuate during the course of the day.

Delirium is common in hospital

10% of patients aged 70 and over have delirium on admission to hospital

Up to 80% of patients aged 70 and over in intensive care have delirium

Patients with dementia are 6x more likely to develop delirium

Patients with delirium are at a greater risk of harm

30-40%

Delirium is easier to prevent than to treat. 30-40% of cases are preventable

50% of the time delirium is misdiagnosed, not detected or not identified in hospital

Not recognising delirium is a safety and quality issue

Patients with delirium have more falls, pressure injuries, functional decline and ongoing cognitive difficulties

Patients with delirium are more likely to die

45% of delirium in older patients is unresolved on discharge from hospital

Patients with delirium are 2x more likely to go into residential care prematurely after discharge

We can improve hospital care of patients with delirium

Be alert to delirium and the risk of harm for patients

Recognise and respond to patients with delirium

Provide safe and high-quality care tailored to the needs of patients with delirium
